

Insertion sort

Algorithm

The simple steps of achieving the insertion sort are listed as follows -

Step 1 - If the element is the first element, assume that it is already sorted. Return 1.

Step2 - Pick the next element, and store it separately in a **key**.

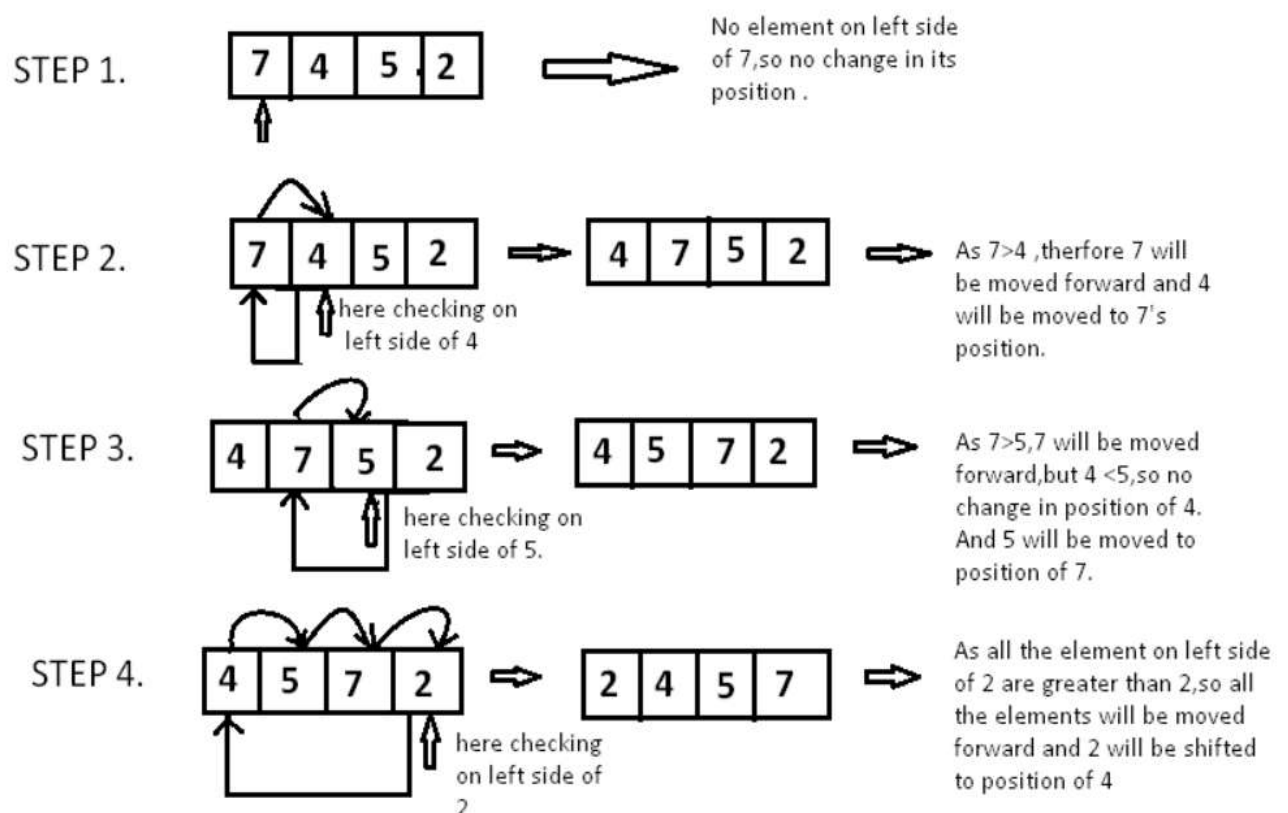

Step3 - Now, compare the **key** with all elements in the sorted array.

Step 4 - If the element in the sorted array is smaller than the current element, then move to the next element. Else, shift greater elements in the array towards the right.

Step 5 - Insert the value.

Step 6 - Repeat until the array is sorted.

Take array $A[] = [7, 4, 5, 2]$.

Example 2

The array to be sorted is as follows:

10	2	6	15	4	1
----	---	---	----	---	---

Now for each pass, we compare the current element to all its previous elements. So in the first pass, we start with the second element.

Pass 1:

10	2	6	15	4	1
----	---	---	----	---	---

=> compare 2nd element to 1st element before it and sort

Pass 2:

2	10	6	15	4	1
---	----	---	----	---	---

=> compare 3rd element to all elements before it and sort

Pass 3:

2	6	10	15	4	1
---	---	----	----	---	---

=> compare 4th element to all elements before it and sort

Pass 4:

2	6	10	15	4	1
---	---	----	----	---	---

=> compare 5th element to all elements before it and sort

Pass 5:

2	4	6	10	15	1
---	---	---	----	----	---

=> compare 5th element to all elements before it and sort

Pass 6:

1	2	4	6	10	15
---	---	---	---	----	----

=> sorted array

Thus, we require N number of passes to completely sort an array containing N number of elements.

As shown in the illustration above, at the end of each pass, one element goes in its proper place.
